In [14]:

```
import numpy as np
from matplotlib import pyplot as plt
%matplotlib inline
```

The MNIST dataset

The MNIST dataset is composed of 70,000 28×28 grayscale images of handwritten digits. It is represented as a $70000 \times 28 \times 28$ numpy array (a "3d matrix").

In [15]:

```
x = np. load("mnist.npy")
print(x. shape)
(70000, 28, 28)
```

Display the first few digits in the dataset.

In [16]:

```
for i in range(5):
    plt. imshow(x[i], cmap="gray")
    plt. show()

5-

10-

20-

25-
```

Computing and diagonalizing the covariance of MNIST

We will interpret each image as a vector in \mathbb{R}^d with $d=28^2=768$. The dataset can thus be seen as a matrix $in\mathbb{R}^{n\times d}$ where n=70000.

In [17]:

```
xx = x. reshape((x. shape[0], -1))
xx
```

Out[17]:

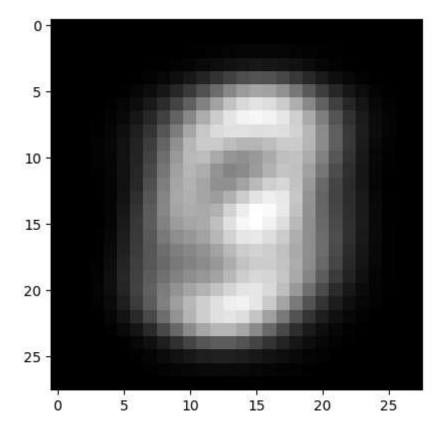

1. Compute the mean $\mu \in \mathbb{R}^d$ of the MNIST dataset and plot it as a 28×28 image.

In [18]:

```
# Your answer here
mean_vector = xx.mean(axis=0)
mean_image = mean_vector.reshape((28, 28))
plt.imshow(mean_image, cmap="gray")
```

Out[18]:

<matplotlib.image.AxesImage at 0x23ec5285fc0>

2. Compute the covariance $\Sigma \in \mathbb{R}^{d \times d}$ of the MNIST dataset and diagonalize it using the function np. linalg. eigh .

In [19]:

```
# Your answer here
cov_matrix = (1 / xx.shape[0]) * (xx - mean_vector).T@ (xx - mean_vector)
eigenvalues, eigenvectors = np. linalg. eigh(cov_matrix)
eigenvalues, eigenvectors

PCA compression of MNIST

4. Let $k \in \mathbb{N}$. Compute the k-dimensional PCA approximation z_1, \ldots, z_n of the MNIST dataset using the eigenvectors u_1, \ldots, u_k . Then, compute the reconstructed images $\hat{x}_i = \mu + z_{i,1}u_1 + \cdots + z_{i,k}u_k$, which are equal to the mean μ plus the orthogonal projection of $x_i - \mu$ on $\mathrm{Span}(u_1, \ldots, u_k)$. Display the first 5 reconstructed images $\hat{x}_1, \ldots, \hat{x}_5$. Choose a small value of k that still allows recognizing the digits.
